

What problem does cloud computing solve at its core?

Cloud computing facilitates the ability for businesses to take their traditional IT infrastructure; consisting of on-premise physical servers costing them tens of thousands of dollars throughout its average seven year lifecycle to operate & maintain, and move their workload to the "cloud"; where service providers host hundreds of physical servers in data centers all across the world and due to economies of scale, is an extremely efficient and therefore cost effective move for the customer as well as an extremely profitable venture for the provider. At its core, cloud computing solves business needs for efficient, scalable, cost-effective, and secure IT workload.
